

Project Report: Adaptive Traffic Signal Control System using Learning Agent

Name: Aryan Kumar

Registration No: 25BAI11257

1. Executive Summary

Traffic congestion is a pervasive issue in urban environments, frequently exacerbated by traditional, fixed-time traffic signals that cannot adapt to real-time conditions. This project addresses this inefficiency by simulating an intelligent traffic signal control system. By utilizing a simple learning agent, the system dynamically adjusts green signal timings based on live traffic density, aiming to optimize traffic flow and reduce wait times.

2. System Methodology & Learning Approach

Unlike conventional static systems, this project acts as an intelligent agent, mimicking the fundamental principles of reinforcement learning through a continuous loop of observation, action, and feedback:

- **Observation (Input):** The system continuously monitors the number of vehicles and classifies the current traffic density into three distinct categories: High, Medium, or Low.
- **Action:** Based on the classification, the system dynamically adjusts the signal duration. For example, it allocates more time during High Traffic periods and reduces the duration during Low Traffic periods.

- **Feedback (Reward/Penalty):** The system evaluates the effectiveness of its timing adjustments using a reward-based mechanism. It stores these experiences to inform and improve future timing decisions.

3. Key Features & Simulation Output

The system is designed to provide both analytical insights and visual feedback regarding its performance.

Core Capabilities:

- Continuous traffic density analysis.
- Dynamic, on-the-fly signal timing adjustments.
- Automatic identification of peak and low traffic periods.

Simulation Outputs:

- A console-based interface simulating the traffic signals and the agent's real-time decisions.
- Graphical visualizations that plot how signal timings adapt and respond to traffic patterns over time.

4. Technical Specifications

The project is built entirely in Python and leverages industry-standard data science libraries to handle logic and visualization.

- Core Language: Python
- Data Handling: pandas (used for managing simulation data and state)
- Visualization: matplotlib (used for graphing traffic patterns and adaptation metrics)

- Execution: The simulation is run via a central main.py script, with dependencies managed through a requirements.txt file.

5. Future Enhancements

While the current simulation effectively demonstrates the core concept, several avenues for advanced development have been identified:

- Real-World Integration: Connecting the system to live IoT traffic sensors and external APIs for real-time data ingestion.
- Advanced Machine Learning: Upgrading the simple reward mechanism to implement robust reinforcement learning algorithms, such as Q-learning.
- System Expansion: Scaling the logic from a single intersection to a comprehensive multi-intersection traffic management network.
- User Interface: Developing a dedicated Graphical User Interface (GUI) to replace the console-based output.

6. Conclusion & Learning Outcomes

This project serves as a highly practical application of intelligent agent systems to solve real-world urban infrastructure problems. It successfully demonstrates the integration of basic machine learning concepts, data analysis, and visual reporting using Python.
